## Identification of the long-run $\beta$ structure

A graduate course in the Cointegrated VAR model: Special topics in Rome

Katarina Juselius<br>University of Copenhagen

November 2011

## Identification when data are nonstationary

Two different identification problems: identification of the long-run structure (i.e., of the cointegration relations) and identification of the short-run structure (i.e., of the equations of the system). The former is about imposing long-run economic structure on the unrestricted cointegration relations, the latter is about imposing short-run dynamic adjustment structure on the equations for the differenced process.

The (short-run) reduced-form representation:

$$
\begin{equation*}
\Delta x_{t}=\Gamma_{1} \Delta x_{t-1}+\alpha \beta^{\prime} x_{t-1}+\Phi D_{t}+\varepsilon_{t}, \quad \varepsilon_{t} \sim \operatorname{IN}(0, \Omega) \tag{1}
\end{equation*}
$$

and then pre-multiply (1) with a nonsingular $p \times p$ matrix $A_{0}$ to obtain the so called (short-run) structural-form representation (2):

$$
\begin{equation*}
A_{0} \Delta x_{t}=A_{1} \Delta x_{t-1}+a \beta^{\prime} x_{t-1}+\tilde{\Phi} D_{t}+v_{t}, \quad v_{t} \sim \operatorname{IN}(0, \Sigma) \tag{2}
\end{equation*}
$$

where $\lambda_{R F}=\left\{\Gamma_{1}, \alpha, \beta, \Phi, \Omega\right\}$ and $\lambda_{S F}=\left\{A_{0}, A_{1}, a, \beta, \tilde{\Phi}, \Sigma\right\}$ are unrestricted.

To distinguish between parameters of the long-run and the short-run structure, we partition $\lambda_{R F}=\left\{\lambda_{R F}^{S}, \lambda_{R F}^{L}\right\}$, where $\lambda_{R F}^{S}=\left\{\Gamma_{1}, \alpha, \Phi, \Omega\right\}$ and $\lambda_{R F}^{L}=\{\beta\}$ and $\lambda_{S F}=\left\{\lambda_{S F}^{S}, \lambda_{S F}^{L}\right\}$, where $\lambda_{S F}^{S}=\left\{A_{0}, A_{1}, a, \tilde{\Phi}, \Sigma\right\}$ and $\lambda_{S F}^{L}=\{\beta\}$. The relation between $\lambda_{R F}^{S}$ and $\lambda_{S F}^{S}$ is given by:

$$
\Gamma_{1}=A_{0}^{-1} A_{1}, \alpha=A_{0}^{-1} a, \varepsilon_{t}=A_{0}^{-1} v_{t}, \quad \Phi=A_{0}^{-1} \tilde{\Phi}, \Omega=A_{0}^{-1} \Sigma A_{0}^{\prime-1}
$$

The short-run parameters of the reduced form, $\lambda_{R F}^{S}$, are uniquely defined, whereas those of the structural form, $\lambda_{S F}^{S}$, are not, without imposing $p(p-1)$ just-identifying restrictions. The long-run parameters $\beta$ are uniquely defined based on the normalization of the eigenvalue problem. This need not coincide with an economic identification, and in general we need to impose $r(r-1)$ just-identifying restrictions on $\beta$. Because the long-run parameters remain unaltered under linear transformations of the VAR model, $\beta$ is the same both in both forms and identification of the long-run structure can be done based on either the reduced form or the structural form.

## Three aspects of identification

- generic (formal) identification, which is related to a statistical model
- empirical (statistical) identification, which is related to the actual estimated parameter values, and
- economic identification, which is related to the economic interpretability of the estimated coefficients of a formally and empirically identified model.

## Identifying restrictions on all cointegration relations

As before, $R_{i}$ denotes a $p 1 \times m_{i}$ restriction matrix and $H_{i}=R_{i \perp}$ a $p 1 \times s_{i}$ design matrix $\left(m_{i}+s_{i}=p 1\right)$ so that $H_{i}$ is defined by $R_{i}^{\prime} H_{i}=0$. Thus, there are $m_{i}$ restrictions and consequently $s_{i}$ parameters to be estimated in the $i$ th relation. The cointegrating relations are assumed to satisfy the restrictions $R_{i}^{\prime} \beta_{i}=0$, or equivalently $\beta_{i}=H_{i} \varphi_{i}$ for some $s_{i}$-vector $\varphi_{i}$, that is

$$
\begin{equation*}
\beta=\left(H_{1} \varphi_{1}, \ldots, H_{r} \varphi_{r}\right) \tag{3}
\end{equation*}
$$

The linear restrictions do not specify a normalization of the vectors $\beta_{i}$. The rank condition requires that the first cointegration relation, for example, is identified if

$$
\begin{equation*}
\operatorname{rank}\left(R_{1}^{\prime} \beta_{1}, \ldots, R_{1}^{\prime} \beta_{r}\right)=\operatorname{rank}\left(R_{1}^{\prime} H_{1} \varphi_{1}, \ldots, R_{1}^{\prime} H_{r} \varphi_{r}\right)=r-1 \tag{4}
\end{equation*}
$$

This implies that no linear combination of $\beta_{2}, \ldots, \beta_{r}$ can produce a vector that "looks like" the coefficients of the first relation

## Formulation of identifying hypotheses and identification rank conditions

$$
\left[\begin{array}{ccccc}
\beta_{11}^{c} & -\beta_{11}^{c} & 0 & \beta_{12}^{c} & -\beta_{12}^{c}  \tag{5}\\
0 & \beta_{21}^{c} & \beta_{22}^{c} & 0 & \beta_{23}^{c} \\
0 & 0 & 0 & \beta_{31}^{c} & \beta_{32}^{c}
\end{array}\right]\left[\begin{array}{c}
m_{t}^{r} \\
y_{t}^{r} \\
\Delta p_{t} \\
R_{m, t} \\
R_{b, t}
\end{array}\right]
$$

The number of restrictions $m_{i}$ and the number of free parameters $s_{i}$ in each beta! The rank conditions are given by:

| Relation | $R_{i . j}$ | Relation | $R_{i . j k}$ |
| :---: | :---: | :---: | :---: |
| 1.2 | 3 | 1.23 | 3 |
| 1.3 | 1 |  |  |
| 2.1 | 2 | 2.13 | 2 |
| 2.2 | 1 |  |  |
| 3.1 | 1 | 3.12 | 3 |
| 3.2 | 2 |  |  |

## Normalization

The parameters $\left(\beta_{11}^{c}, \beta_{12}^{c}\right),\left(\beta_{21}^{c}, \beta_{22}^{c}, \beta_{23}^{c}\right)$ and $\left(\beta_{31}^{c}, \beta_{32}^{c}\right)$ are defined up to a factor of proportionality, and one can always normalize on one element in each vector without changing the likelihood:

$$
\left[\begin{array}{ccccc}
1 & -1 & 0 & \beta_{12}^{c} / \beta_{11}^{c} & -\beta_{12}^{c} / \beta_{11}^{c}  \tag{6}\\
0 & 1 & \beta_{22}^{c} / \beta_{21}^{c} & 0 & \beta_{23}^{c} / \beta_{21}^{c} \\
0 & 0 & 0 & 1 & \beta_{32}^{c} / \beta_{31}^{c}
\end{array}\right]\left[\begin{array}{c}
m_{t}^{r} \\
y_{t}^{r} \\
\Delta p_{t} \\
R_{m, t} \\
R_{b, t}
\end{array}\right]
$$

When normalizing $\beta_{i}^{c}$ by diving through with a non-zero element $\beta_{i j}^{c}$, the corresponding $\alpha_{i}^{c}$ vector is multiplied by the same element. Thus, normalization does not change $\Pi=\alpha_{i}^{c} \beta_{i}^{c \prime}=\alpha \beta^{\prime}$ and we can choose whether to normalize or not. However, when identifying restrictions have been imposed on the long-run structure, it is only possible to get standard errors of $\hat{\beta}_{i j}$ when each cointegration vector has been properly normalized.

## Calculation of degrees of freedom

Given that the restrictions are identifying the degrees of freedom can be calculated from the following formula:

$$
v=\sum\left(m_{i}-(r-1)\right) .
$$

Consider the above example where $s_{i}$ is the number of free coefficients in $\beta_{i}^{c}$, and $m_{i}=p-s_{i}$ the total number of restrictions on vector $\beta_{i}^{c}$. The degrees of freedom are calculated as:

| $s_{i}$ | $s_{1}=2$ | $s_{2}=3$ | $s_{3}=2$ |
| :---: | :---: | :---: | :---: |
| $m_{i}$ | $m_{1}=3$ | $m_{2}=2$ | $m_{3}=3$ |
| $r-1$ | 2 | 2 | 2 |
| $m_{i}-(r-1)$ | 1 | 0 | 1 |

so the degrees of freedom are $v=2$. Some restrictions may not be identifying (for example the same restriction on all cointegration relations), but are nevertheless testable restrictions.

## Just-identifying restrictions

One can always transform the long-run matrix $\Pi=\alpha \beta^{\prime}$ by a nonsingular $r \times r$ matrix $Q$ in the following way: $\Pi=\alpha Q Q^{-1} \beta^{\prime}=\tilde{\alpha} \tilde{\beta}^{\prime}$, where $\tilde{\alpha}=\alpha Q$ and $\tilde{\beta}=\beta Q^{\prime-1}$. We will now demonstrate how to choose the matrix $Q$ so that it imposes $r-1$ just-identifying restrictions on each $\beta_{i}$. An example of a just identified long-run reduced form structure can be found as follows:

$$
\beta=\left[\begin{array}{ccc}
\beta_{11} & \beta_{12} & \beta_{13} \\
\beta_{21} & \beta_{22} & \beta_{23} \\
\beta_{31} & \beta_{32} & \beta_{33} \\
\cdots & \cdots & \cdots \\
\beta_{41} & \beta_{42} & \beta_{43} \\
\beta_{51} & \beta_{52} & \beta_{53}
\end{array}\right]=\left[\begin{array}{c} 
\\
\beta_{1} \\
\ldots \\
\beta_{2}
\end{array}\right] ; \quad \beta_{1}^{-1}\left[\begin{array}{c} 
\\
\beta_{1} \\
\ldots \\
\beta_{2}
\end{array}\right]=\left[\begin{array}{ccc}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1 \\
\cdots & \cdots & \cdots \\
\widetilde{\beta}_{41} & \widetilde{\beta}_{42} & \widetilde{\beta}_{43} \\
\widetilde{\beta}_{51} & \widetilde{\beta}_{52} & \widetilde{\beta}_{53}
\end{array}\right]
$$

We choose the design matrix $Q=\left[\beta_{1}\right]$ where $\beta_{1}$ is a $(r \times r)$ nonsingular matrix defined by $\beta^{\prime}=\left[\beta_{1}, \beta_{2}\right]$. In this case $\alpha \beta^{\prime}=\alpha\left(\beta_{1} \beta_{1}^{-1 \prime} \beta^{\prime}\right)=\alpha[I, \tilde{\beta}]$ where $I$ is the $(r \times r)$ unit matrix and $\tilde{\beta}=\beta_{1}^{-1 \prime} \beta_{2}$ is a $r \times(p-r)$ matrix of full rank.

The above example for $x_{t}=\left[x_{1 t}^{\prime}, x_{2 t}^{\prime}\right]^{\prime}$, where $x_{1 t}^{\prime}=\left[x_{1 t}, x_{2 t}, x_{3 t}\right]$ and $x_{2 t}^{\prime}=\left[x_{4 t}, x_{5 t}\right]$, would describe an economic application where the three variables in $x_{1 t}$ are 'endogenous' and the two in $x_{2 t}$ are 'exogenous'.
Furthermore, if we decompose $\alpha=\left[\begin{array}{l}\alpha_{1} \\ \alpha_{2}\end{array}\right]$ and $\alpha_{2}=0$, then $\beta^{\prime} x_{t}$ does not appear in the equation for $\Delta x_{1, t}$ and $x_{2, t}$ is weakly exogenous for $\beta$. In this case, efficient inference on the long-run relations can be conducted in the conditional model of $\Delta x_{1, t}$, given $\Delta x_{2, t}$. When 'endogenous' and 'exogenous' are given an economic interpretation this corresponds to the triangular representation suggested by Phillips (1990). Note that the latter requires that $\alpha_{2}=0$, which is a testable hypothesis.

## Over-identifying restrictions

Consider the structure:

$$
\mathcal{H}_{S .3}: \beta=\left(H_{1} \varphi_{1}, H_{2} \varphi_{2}, H_{3} \varphi_{3}\right),
$$

where

$$
H_{1}=\left[\begin{array}{cc}
1 & 0 \\
-1 & 0 \\
0 & 0 \\
0 & 0 \\
0 & 0 \\
0 & 1
\end{array}\right], H_{2}=\left[\begin{array}{lll}
0 & 0 & 0 \\
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 1
\end{array}\right], H_{3}=\left[\begin{array}{ccc}
0 & 0 & 0 \\
0 & 0 & 0 \\
1 & 0 & 0 \\
-1 & -1 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{array}\right] .
$$

Which are the $\beta$-relations?

Table: The rank conditions for identifiction

| $r_{i . j}$ | $\mathcal{H}_{S .3}$ | $\mathcal{H}_{S .4}$ | $r_{i . j g}$ | $\mathcal{H}_{S .3}$ | $\mathcal{H}_{S .4}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1.2 | 2 | 2 | 1.23 | 4 | 3 |
| 1.3 | 2 | 1 |  |  |  |
| 2.1 | 1 | 2 | 2.13 | 3 | 3 |
| 2.3 | 2 | 2 |  |  |  |
|  |  |  |  |  |  |
| 3.1 | 1 | 1 | 3.12 | 3 | 3 |
| 3.2 | 2 | 2 |  |  |  |

The degrees of freedom in the test of overidentifying restrictions are given by $v=\Sigma_{i}\left(m_{i}-r+1\right)$, where $m_{i}$ is the number of restrictions on $\beta_{i}$. The degrees of freedom for $\mathcal{H}_{s .3}$ are calculated as:

$$
v=\sum_{i=1}^{r} m_{i}-(r-1)=(4-2)+(3-2)+(3-2)=2+1+1=4
$$

The corresponding LR test statistic became $\chi^{2}(4)=4.05$ with a p-value of 0.40 , so the structure can be accepted.
The degrees of freedom of the hypothesis $\mathcal{H}_{S .4}$ are calculated as:

$$
v=\sum_{i=1}^{r} m_{i}-(r-1)=(3-2)+(3-2)+(3-2)=3 .
$$

The test statistic became $\chi^{2}(3)=2.84$ with a p-value of 0.42 . Thus, both $\mathcal{H}_{S .3}$ and $\mathcal{H}_{S .4}$ are acceptable long-run structures with almost the same p-value. Which one should be chosen?
